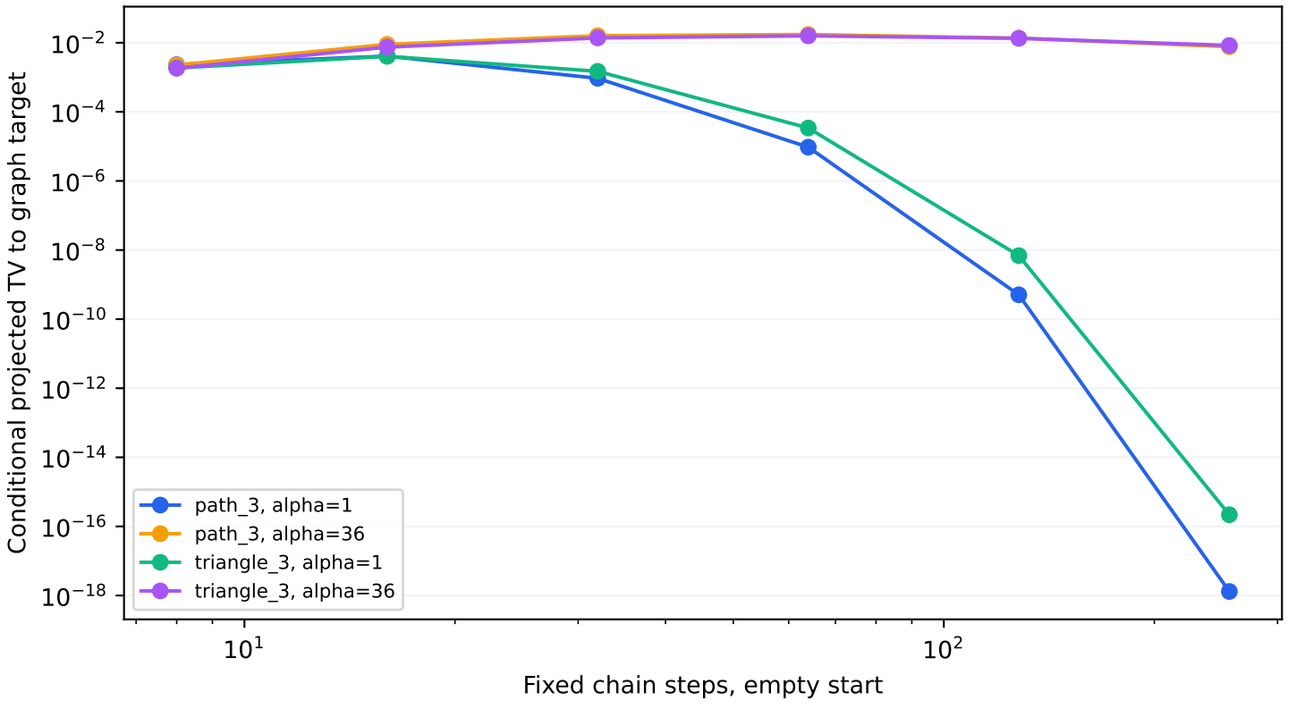
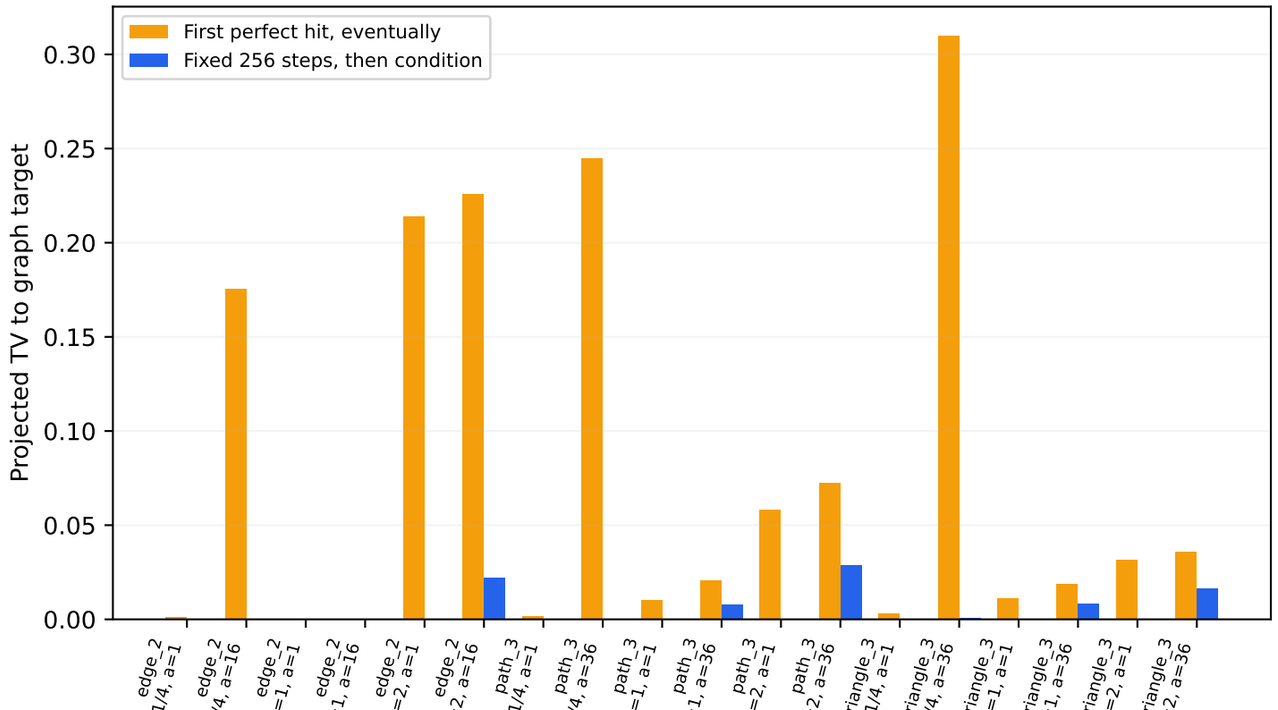
Iteration 64 | Actual matching chains, finite words and stopping laws

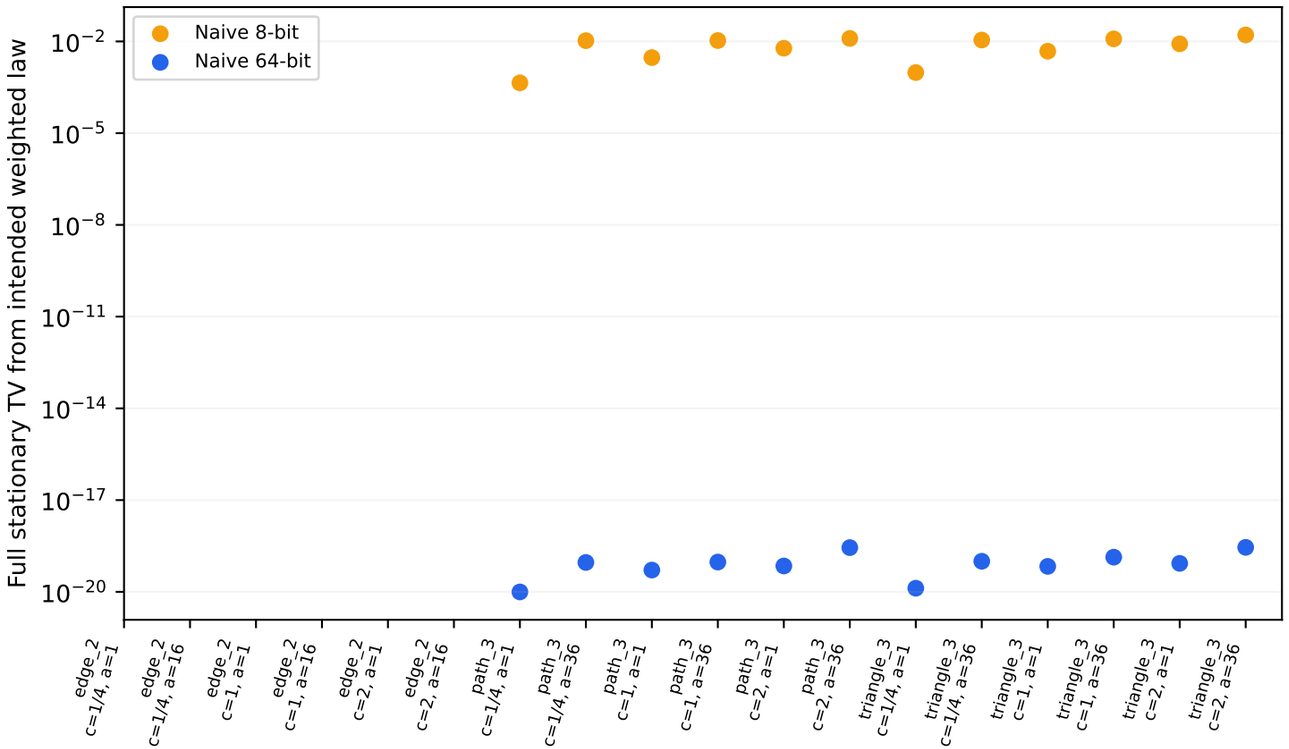
A Exact-word chain: c=1, nontrivial graph panel



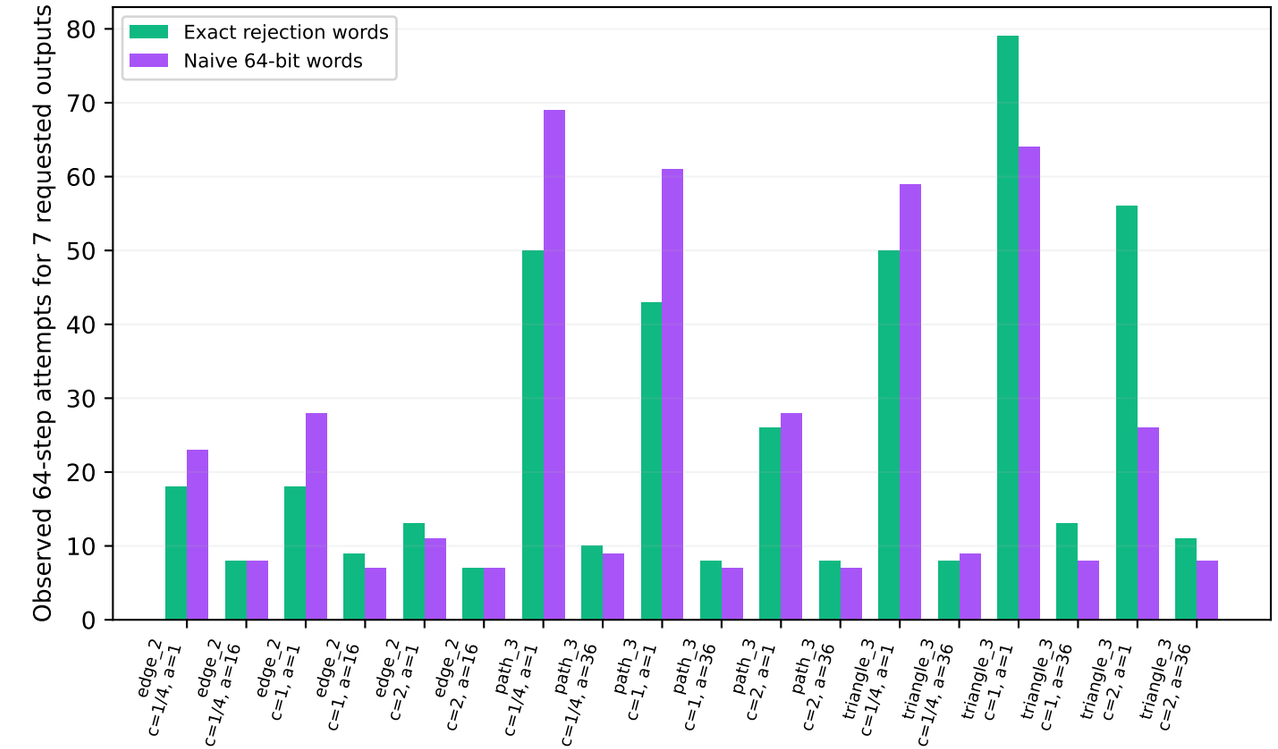
B Different stopping rules produce different laws



C Quantized selection / acceptance can bias equilibrium



D Public trajectories, not a throughput benchmark



5 fixed graphs x 3 c values x 2 edge multipliers; at most 32 matching states. Exact finite-time laws, not large-system mixing certificates.
Public output uses independent restarted 64-step attempts, capped at 64; any failure remains explicit. First-hit is an audited comparator, not the sampler.
